EMI Filters

Electro Magnetic Interference in its simplest definition is electrical ‘noise’ on a signal or power line. Radio Frequency Interference is Electro Magnetic Interference (EMI) which affects radio frequencies.

Modern electronics are susceptible to interference and increasingly protection against EMI is a legislative, contractual and safety requirement for telecommunications, avionics, industrial and defence equipment. Many circuits are particularly sensitive to voltage transients or spikes on signal and control lines making them acutely vulnerable to EMI.

Therefore it is essential that equipment operating within this potentially hostile environment is compliant with worldwide electromagnetic standards & legislation to provide both protection and reliability.

There are many routes to ensure that electrical and electronic equipment meets directives on electromagnetic compatibility (EMC). EMC means that equipment has the ability to function as designed, without being adversely affected by an electromagnetic interference and without being the source of such interference.

EMI can be caused by a number of factors; power supplies, high bandwidth signals, radar & radio sources, aerials, high current flows or switching, radar transmitters, motors, computer clocks, electrostatic discharge and of course natural electrical disturbances such as lightning.

The effects of EMI can vary, from image or sound degradation ('snow' or 'hum') through unexpected switching or resetting of controllers to the most severe cases which can lead to total system failure.

Anyone manufacturing, supplying or using critical components, products and systems simply cannot afford to take chances with EMI. This is especially relevant in the defence industry and aerospace where safety and reliability are paramount.

Many of the most critical systems which must be protected against EMI are used by the military but it can also be a factor in a huge range of other areas. For example:

- EMI ‘noise’ from the subway system caused the failure of Rubens Barrichello’s gearbox in the Monaco Grand Prix.
- EMI from a signal booster disrupted pilot to air traffic control communication at Luton Airport.
- EMI emanating from new trains introduced in Connecticut caused the track signals to fail.
- EMI generated by a walkie-talkie being used at the Davis-Besse nuclear power plant in Ohio disabled the plant’s emergency shutdown system.

So EMI is a threat that has to be taken seriously.

Manufacturers have a dual responsibility. They must ensure that their equipment is protected against EMI. But they must also ensure that their equipment does not cause problems for other equipment or systems. That means EMI filtering is now an essential element of electrical and electronic equipment design.

EMI Protection

Protecting equipment against EMI requires effective screening. The simplest method is to enclose the equipment in a metal conductive box or ‘Faraday cage’.

However, in practical terms most equipment requires input and output connections, power cables and signal or control wiring. This cabling can act as antennae – transmitting and receiving the interference, and introducing electrical ‘noise’ which in turn contaminates other wires and circuits.

This EMI contamination can be countered by capacitive (C) and inductive (L) filtering. The primary function of a filter is to attenuate or reduce the intensity of the high frequency or radio frequency (RF) currents and voltages, which would otherwise cause interference. Low pass filters are designed to pass all frequencies below a specific cut-off level.

A capacitor acts as a ‘path to ground/earth’ for signals but only at high frequency – which is where the ‘noise’ is located. Inductors reject the ‘noise’ back down the line, but allow DC signals to pass through. EMC filter products also incorporate Transient Voltage Suppression (TVS) in many cases to protect against harmful voltage spikes.

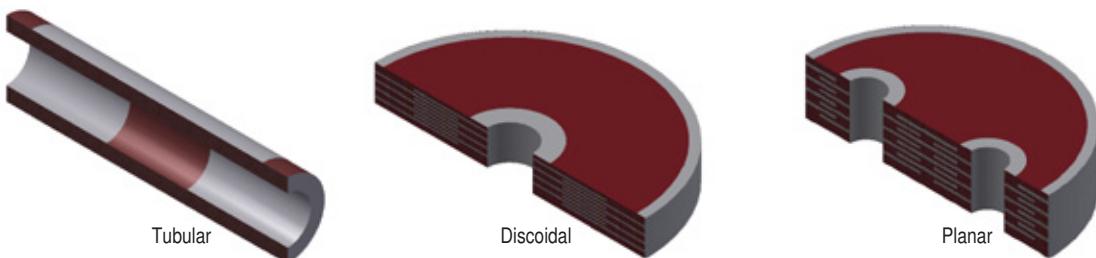

Combinations of C and L configuration filters can be specified to deliver various performance characteristics determined the level of attenuation (reduction in intensity) required at various frequencies.

To allow comparison insertion attenuation calculations assume a 50Ω system but variations to source and load impedances of the circuit can have a great effect and should be considered when selecting the filter configuration.

CONFIGURATION	CIRCUIT CONFIGURATION	APPLICATIONS AND ADVANTAGES
C		<ul style="list-style-type: none"> • Higher impedance • Simple construction • Low cost
L		<ul style="list-style-type: none"> • Used when source and load impedances are different • Low cost • Increased filtering at high frequencies
Pi		<ul style="list-style-type: none"> • High impedance systems • Steep interference cut off response
T		<ul style="list-style-type: none"> • Low impedance systems • Steep interference cut off response
2Pi		<ul style="list-style-type: none"> • High impedance systems • Low cut off frequency
2T		<ul style="list-style-type: none"> • Low impedance systems • Low cut off frequency

Most high performance filter solutions utilise one or more of three capacitor technologies:

- single layer tubular capacitors (dry pressed and extruded)
- multilayer discoidal capacitors
- multilayer capacitor planar arrays – custom-designed solutions which achieve multiway filtering in a compact design

These translate into a range of products:

- **Filtered connectors** integrated into a custom shell or added to a standard shell. Easy and cost effective to assemble in large numbers they offer reduced weight and remove the need for bulkhead fittings.
- **Filtered modules & filter arrays** are generally bespoke designs which can utilise any filter technology including Transient Voltage Suppression (TVS) to protect against voltage spikes. They can also integrate non-filter elements in an interconnect solution. The customer benefits from ease of assembly and avoiding additional connector cost or lead-time.
- **Discrete feedthrough filters** incorporate environmental or hermetic sealing and are designed for threaded, solder-in or push-fit bulkhead mounting. They offer a good performance range and high reliability with integrated TVS protection in a wide product base.
- **Surface mount filters** for printed circuit boards offer good electrical performance across a limited range of frequencies, automated assembly and effective environmental sealing.
- **Capacitor planar arrays** are bespoke interconnect solutions with multiline capacitors located within a single ceramic disc, and offer the customer the option of specifying the electrical characteristic for each line. They are highly reliable, reduce assembly complexity and offer a solution with a comparative low cost per line.

Oxley Group - Proven EMI Protection

Oxley has established itself as a world class provider of EMI suppression capability and integrated solutions for defence, aerospace, rail, electronics and telecommunications applications, meeting the needs of global customers requiring uncompromising quality and reliability in demanding environments across military and industrial platforms.

A leading specialist in the effective suppression of electromagnetic interference through standard and advanced filtering solutions including Transient Voltage Suppression (TVS), Oxley offers customers comprehensive design, manufacturing and test facilities for electronic systems and components within the company's UK manufacturing centre and through Oxley Inc. in the USA. That represents an extensive core capability for new product development and a rapid turnaround service - even for customised designs.

Oxley filter solutions are used in a wide range of applications. For military customers that includes vehicles and weaponry including IR rifle sights, man-portable and vehicle communication systems, rocket igniter systems, military generators and aircraft ejector seat control circuits and gun control systems. Within the aerospace sector typical uses are aircraft pressure sensors, aero engine controllers, helicopter weight on ground sensors and obstacle avoidance radars. They are also found in train communication systems, security cameras, and crane remote controls, automated cruise controls in cars and in electrical test equipment.

Facilities at Oxley's UK production centre include a ceramic production capability for discoidal, tubular and multiway capacitors, CNC machining, electro-plating, prototype model shop, tool room and dedicated test area. All products are tested to the most rigorous standards, with on-site high voltage and DC and AC burn-in facilities. Company approvals include: BS EN 9100: Rev C, ISO 9001:2000, ISO 14001:2004 and AS9100C.

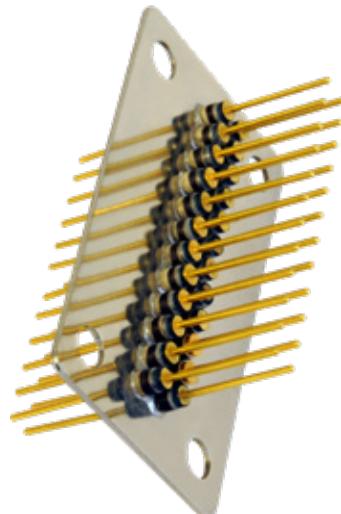

Innovation, quality and reliability are at the heart of the business to develop powerful bespoke capabilities and deliver products that enhance the capability of platforms and systems across the world, laying the foundations of Oxley's comprehensive product portfolio:

EMI Filters - both discrete and multiline

Ceramic planar capacitor arrays

Arrays of discrete filters

Custom filter modules

Filtering of MIL standard connectors

Threaded, solder, press fit and surface mount styles

Understanding the priorities of the customer is a key element for Oxley in delivering high performance, long term reliability and stable performance over the working temperature range. The experience of manufacturing a wide range of components using standard materials and techniques combines with the expertise and insight gained developing thousands of custom-made solutions to offer outstanding customer benefits:

- Proven reliability both through design and on-site dc/ac burn-in facilities to agreed confidence levels.
- Advanced performance through the use of custom-designed ceramic and Transient Voltage Suppression.
- Minimum size and weight achieved by bespoke ceramic and Transient Voltage Suppression.
- Lower customer costs by integrating the filter capability into the connector or module.

MIL-STD-461 and EMI Filters - Explanation

The US MIL-STD-461 specification regulates the control of electromagnetic interference emissions and susceptibility of equipment. It sets requirements for the levels of emissions allowed to be exported from electrical equipment, and the susceptibility levels of equipment from external noise sources. It also provides guidelines on measuring those features.

If the levels of emissions from equipment exceed the limits set in MIL-STD-461, then they need to be attenuated (reduced in intensity) using an EMI filter. The performance of that filter across the frequency spectrum must allow the equipment emissions to be suppressed to a level low enough to allow the equipment to claim compliance with the limits of the specification. That filter performance requirement is determined by the electromagnetic signature of the equipment, and the specified limits. Compliance can then be verified by test and measurement.

Therefore no filter manufacturer can claim that their filters "meet" MIL-STD-461; because it is the equipment or platform which "meets" the specification - not the filter.

Key Characteristics

Applications

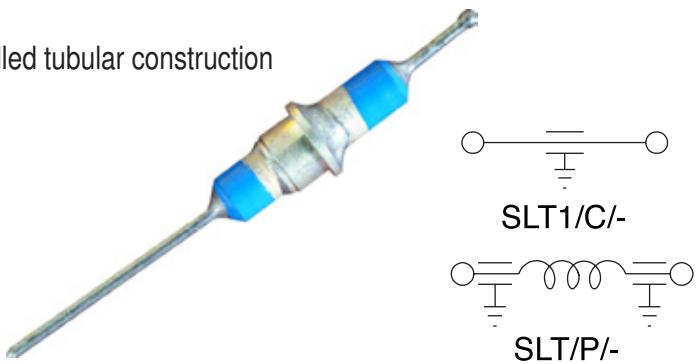

- High density panels
- Bulkhead filter arrays

Performance

- $\leq 5\text{nF}$
- $\leq 400\text{Vdc}$
- High frequency
- Temperature -55°C to $+125^\circ\text{C}$

Rugged

- Robust thick walled tubular construction

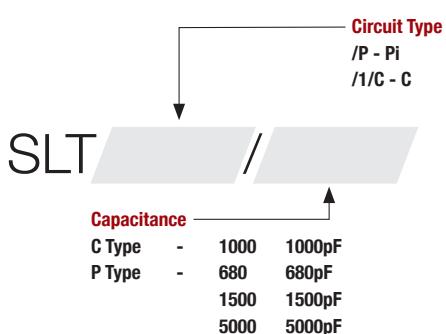

Electrical Characteristics

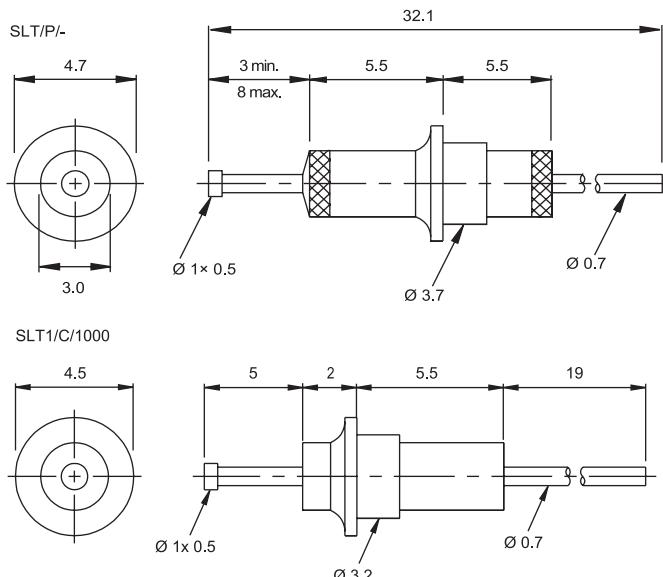

Circuit	Cap	Current	Voltage dc	I.L. (dB) 1MHz	10 MHz	100 MHz	1 GHz	10 GHz	Colour Code
C	1000pF	10A	400v	-	5	24	40	65	-
P	680pF	10A	200v*	-	4	35	60	70	Green
P	1500pF	10A	200v*	1	12	50	75	75	Blue
P	5000pF	10A	200v*	4	25	70	75	75	Red

*Voltage derates linearly to 100v dc from 85°C to 125°C

Ordering Information

Example: SLTP/P/1500 - Pi Circuit, 1500pF

ALL DIMENSIONS IN MM

*Voltage decreases linearly from 85°C to 125°C

Technical Information

BODY & NUT	Tin or Silver
ENVIRONMENTAL CLASSIFICATION	55/125/56

Key Characteristics

Applications

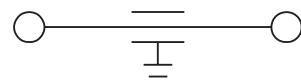

- High Density Panels
- Bulkhead Filter Arrays

Performance

- $\leq 100\text{nF}$
- $\leq 100\text{Vdc}$
- High frequency
- Temperature -40°C to $+100^\circ\text{C}$

Rugged

- Discoidal construction
- High Performance

Technical Information

BODY & NUT	Tin or Silver
ENVIRONMENTAL CLASSIFICATION	55/125/56 Hermetic

*ROHS versions available upon request - please speak to the sales department

Panel Mounted Hermetic L Circuit Filters

[Key Characteristics]**Applications**

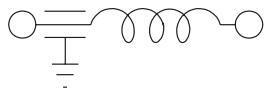

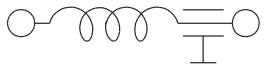

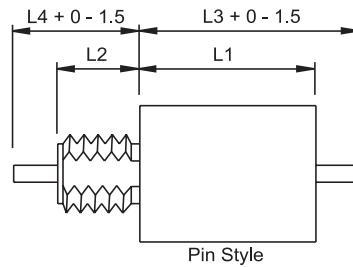

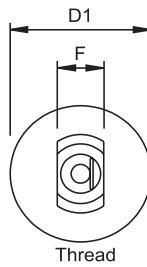

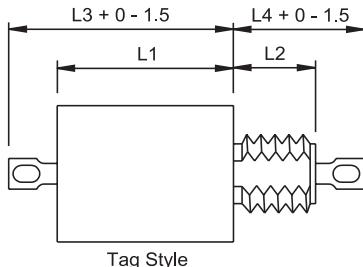

- Panels
- Bulkhead filter arrays

Performance

- $\leq 3\mu\text{F}$
- $\leq 600\text{Vdc}$
- High Frequency
- Temperature -55°C to 125°C

Rugged

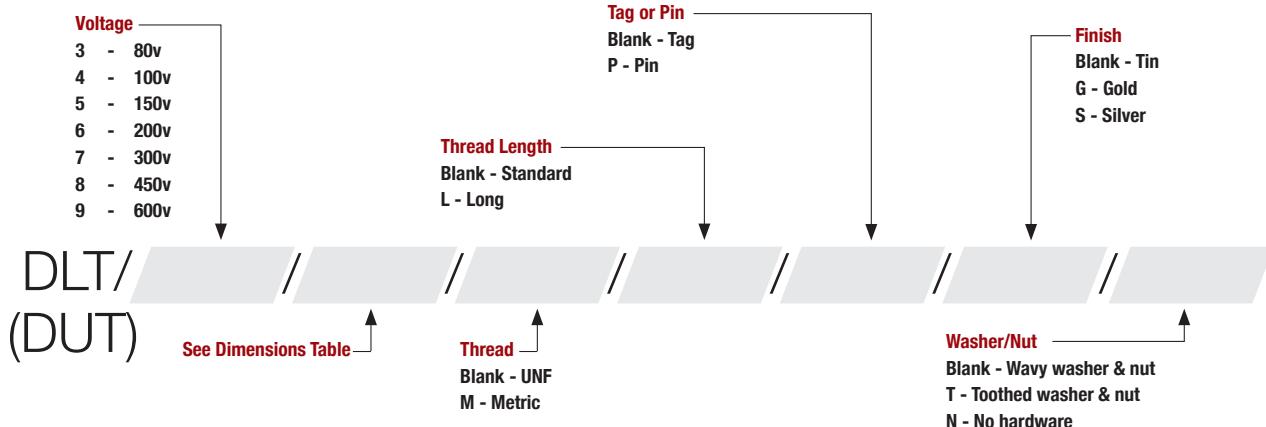

- Discoidal construction

Technical Information

BODY & NUT	Tin or Silver
ENVIRONMENTAL CLASSIFICATIONS	55/125/56 Hermetic

*ROHS versions available upon request - please speak to the sales department

Key Characteristics

Applications

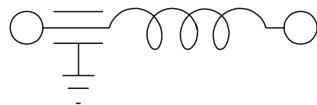

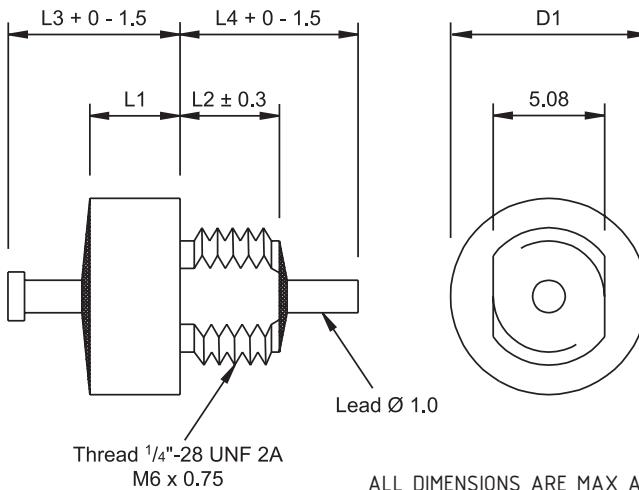

- High Density Panels
- Bulkhead Filter Arrays

Performance

- $\leq 1.4\mu\text{F}$
- $\leq 600\text{Vdc}$
- High frequency
- Temperature -55°C to $+125^\circ\text{C}$

Rugged

- Discoidal construction

THD
END

ALL DIMENSIONS ARE MAX AND IN MM UNLESS OTHERWISE STATED

Product Installation

Due to the nature of the components used in the assembly of ceramic filters, great care must be taken to avoid damage either by mechanical or thermal stress during the installation or termination of the device. Bending or cropping of terminal wires should not be carried out unless adequate support of the wire can be provided to eliminate the possibility of mechanical stress or shock during the cutting operation.

To achieve optimum insertion loss performance, the design of the equipment must be such that it allows for the component to be mounted to a bulkhead of minimal impedance. Co-axial earthing over a full 360° must be achieved and input and output connections should be screened from each other.

LEAD WIRE ATTACHMENT

- 1 To eliminate the risk of thermal shock, the filter assembly should be preheated to 120°C (248°F) for 5 minutes.
- 2 Joints should be effected using a soldering iron with a bit temperature not exceeding 300°C (572°F). To minimise the heat transfer to the filter elements, the solder joint should be completed within a period not exceeding 10 seconds.
- 3 The assembly should be allowed to cool at a rate not exceeding 100°C (212°F) per minute.
- 4 In subsequent degreasing operations, care must be taken to avoid any thermal shock.

Component Mounting

SOLDER STYLE

- 1 The filter and mounting plate must be preheated together to eliminate thermal shock on the ceramic elements. This assembly should be allowed to increase in temperature gradually by soaking in an ambient of 120°C (248°F) for a period of up to 5 minutes where possible. Heat must not be applied directly to the filter body and the temperature on the filter surface should not be allowed to increase faster than by 100°C (212°F) per minute.
- 2 After the preheat cycle, the temperature should be raised to achieve solder flow, not exceeding 250°C. This should be maintained for a minimum period, consistent with a good joint (10 seconds maximum). Forced cooling, e.g. by cleaning must be avoided.

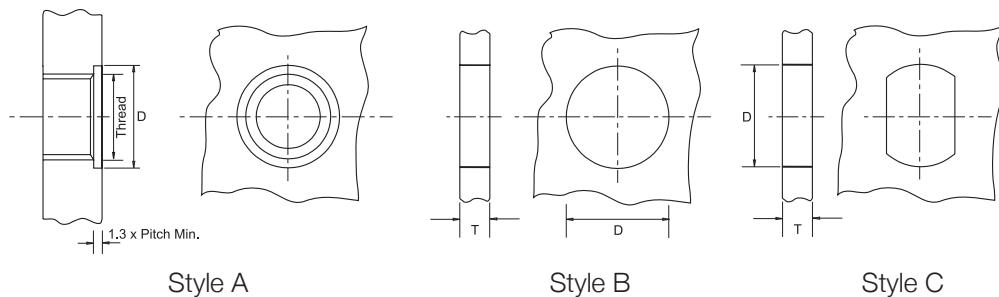

THREADED STYLE

- 1 All thread area and mating surfaces must be clean and dry prior to assembly.
- 2 If a washer is used, this must be fitted between the nut and ground plane. The selection of the washer style - either internal toothed or wavy, must take into consideration the material of the bulkhead. It is recommended that toothed washers should not be used in conjunction with protective finishes such as alochrome.
- 3 If mounting in a threaded hole, the form of the hole should be as style A, which is designed to ensure efficient RF sealing of the assembly by maximizing the mating surface area. For mounting in a plain hole by the use of the supplied mounting hardware, the clearance hole should be as style B or C.
- 4 The maximum panel thickness as detailed for the particular device must not be exceeded. The mounting torque as defined below for the particular style of hole and thread diameter must be observed. No strain should be exerted on the cylindrical part of the filter body or on any of the terminal/seal areas.
- 5 Locking compounds, if used, should be applied after the device has been installed to the correct mounting torque to avoid the danger of mating surface contamination and the subsequent increase in the resistance of the filter to the bulkhead joint (resulting in serious insertion loss degradation).
- 6 When mounting into a threaded hole, the maximum permissible mounting torque applied must be limited to half the value defined for mounting into a non-threaded hold (see table overleaf).

Application Notes

PERFORMANCE MEASUREMENT AND CALCULATIONS

INSERTION LOSS

The performance of low pass filters is often characterised in terms of an insertion loss curve. Insertion loss can be described as the ratio of voltages across the load with and without the filter in the circuit. This is generally defined using a 50Ω input and load impedance, and given in decibels (dB).

$$\text{Insertion Loss (dB)} = 20 \log_{10} (V_1/V_2)$$

Where V_1 is the signal voltage without the filter present and V_2 is the voltage after the filter has been put into the circuit.

All insertion loss figures shown in this catalogue are measured in a 50Ω system.

Since load current increase and temperature excursion reduce the insertion loss of any filter, operation at lower load current and/or temperature excursion than defined in the data tables will result in further gains of insertion loss of typically 3 to 6 dB.

To achieve optimum insertion loss, the filter should be mounted on a bulkhead of minimal RF impedance and provide co-axial earthing over 360° .

INSERTION LOSS CHARACTERISTICS

Figure 4 shows the insertion loss characteristics of various values of simple C style feedthrough filters measured in a 50Ω system.

Insertion Loss Characteristics

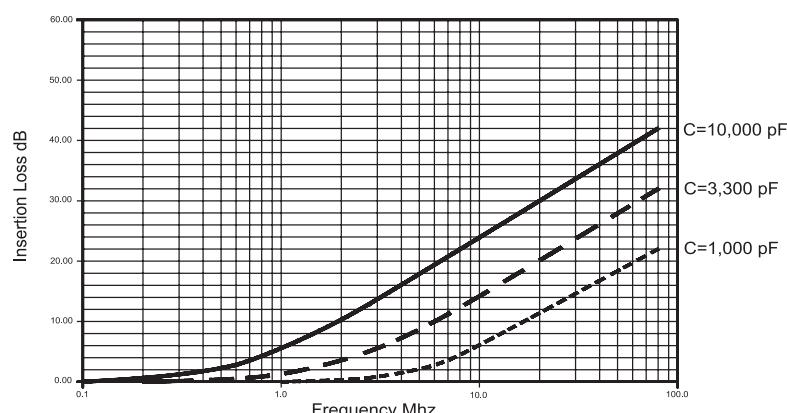

Figure 4 - Insertion Loss of feedthrough capacitor filters

The rising graphs show that the insertion loss rises as the frequency increases above a set point known as the cut-off frequency.

The cut-off frequency is usually defined as the point at which the insertion loss rises above 3 dB. Interference signals at frequencies above the cut-off frequency are increasingly attenuated by the filter. The filter capacitor value must be chosen to ensure that the cut-off frequency is above the desired signal bandwidth. Higher value capacitances result in lower cut-off frequencies, for the same system impedance.

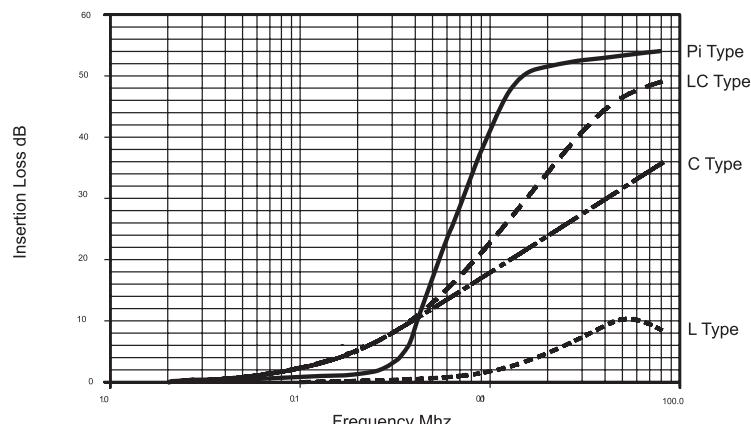

Figure 5 - Insertion Loss for various filter configurations

Figure 5 shows a comparison of typical insertion loss characteristics of different filter configurations. These graphs show that although the insertion loss of an inductive element (L) on its own is very poor, when it is combined with a capacitor to form an LC filter the performance is improved dramatically.

The inductive elements used in many leadthrough filters are in the form of a ferrite bead which has a drop off in attenuation at higher frequencies, leading to the flattening of the high frequency insertion loss response for the L and Pi types.

The responsive curve of the Pi section filter shows an even steeper gradient beyond the cut-off frequency.

In Figures 4 and 5 the characteristics are shown for the filters operating in a 50Ω system, however, the source and load impedance of the circuit in which the filter is operating can have a dramatic effect on the insertion loss. Figure 6 shows the relative low insertion loss of a C type filter operating with a 5Ω source instead of 50Ω . The graph also shows the dramatic improvement when the filter is replaced with an LC type. In this case the inductive element should be connected to the lower impedance side of the circuit.

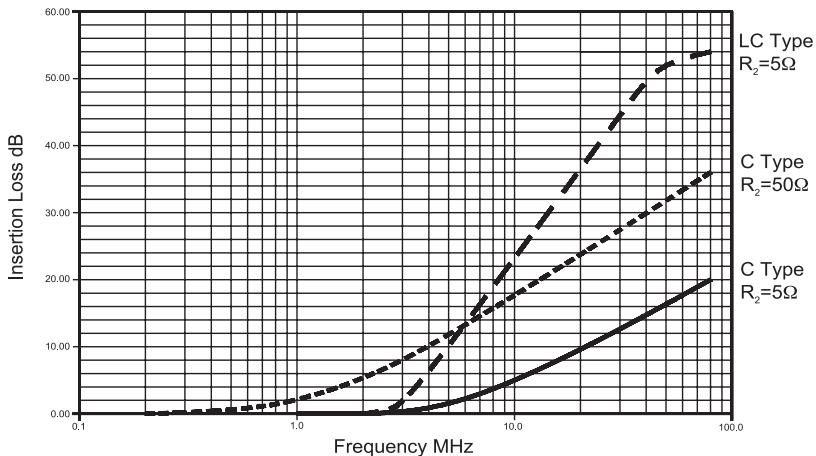

Figure 6 - Use of LC type filters in low impedance systems

CURRENT

The average line current must not exceed the rated current shown in the datasheet. At temperatures in excess of 105°C (221°F), up to a maximum of 125°C (257°F), the maximum current must be derated linearly to 0.6 times the rated current.

The possibility of current transients or surges must be considered. The steady state line current plus the transient or surge current should not be allowed to exceed the following:

- 1.5 times rated current for 10 secs
- 4 times rated current for 500 ms
- 8 times rated current for 50 ms

In filter units incorporating inductors, an increase in line current will reduce the performance of the inductor and hence reduce the level of insertion loss achieved. The insertion loss claimed is only achieved within the load measurement condition defined.

Devices specifying claiming insertion loss at full load current will exhibit higher insertion loss at lower currents.

VOLTAGE

The maximum voltage which may be applied to any filter element must not exceed the voltage rating of the device.

The AC rated voltage is defined for operation up to 125°C (257°F) and for frequencies up to 400 Hz. The peak AC voltage must not exceed the defined DC voltage at 125°C (257°F).

The possibility of voltage transients or spikes must be considered in determining the device voltage.

TEMPERATURE

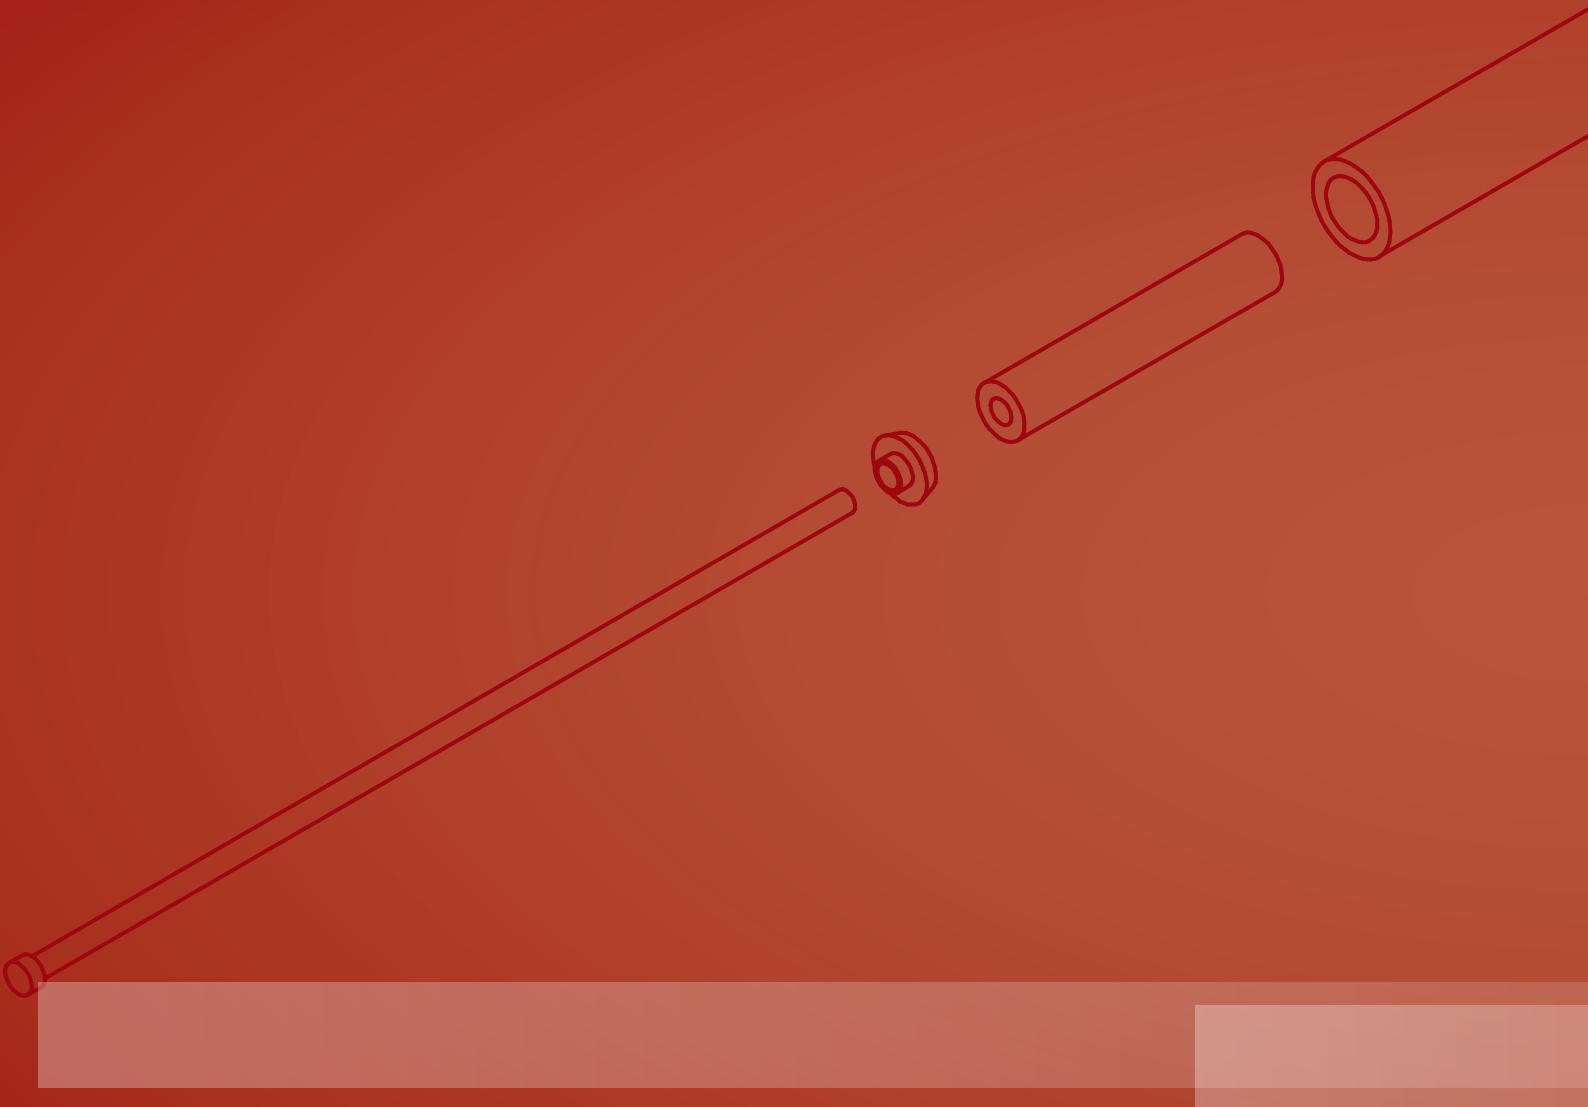

The operating temperature for the device is defined in the specific voltage rating table - normally from -55°C (-67°F) to $+85/+125^\circ\text{C}$ ($+185/+257^\circ\text{F}$). Temperature significantly affects the capacitor value and hence, the insertion loss achieved. The insertion loss claimed is only achieved within the temperature limits defined.

The effect of line current in increasing the temperature of the filter must be remembered. Mounting onto a bulkhead, as well as providing an efficient RF screen, must also provide an efficient heat sink.

The storage temperature of the device must not exceed the operating temperature limits. Extended storage at high ambient temperatures may cause degradation in the solderability of the terminations or discoloration of the finish.

DC VOLTAGE DROP

The effect of the resistance and rated current has been taken into consideration in the temperature rating of the filter. However, the voltage drop at line current should be borne in mind when selecting the current rating of the device. Higher current ratings should be selected if voltage drop must be minimised.
